**ABSTRACT**

Woody species have dramatically increased in density and cover in the semiarid grasslands in southwestern North America during the past 150 years. This brush encroachment involves mostly native species, not uncommonly the dominants being woody members of the Fabaceae. Anthropomorphic factors are mostly responsible, particularly intense grazing pressure from cattle and sheep and fire suppression. At Harris Ranch, Uvalde County, Texas, thorn-scrub woodlands are common. Dominated by thorny woody legume species, the most common taxa are *Senegalia berlandieri* [=*Acacia berlandieri* (guajillo, fern acacia)] and *Senegalia wrightii* [=*Acacia wrightii* (Wright’s senegalia)]. In the two communities studied, these two legume species dominated with importance values between 58 and 159 (possible 200), with 13 to 18 woody and succulent species present in the community. Published on-line www.phytologia.org Phytologia 95(2): 192-201 (May 1, 2013).

**KEY WORDS**: community structure, *Senegalia berlandieri*, *S. wrightii*, thorn-scrub woodland.

Much of the South Texas Plains and the Edwards Plateau once supported a grassland or open savanna with a ground layer of short grasses and forbs. The woody legume *Prosopis glandulosa* (honey mesquite) along with lesser numbers of other shrubs and trees were usually clustered or scattered throughout this grassland (Van Auken 2000). During the past 200 years the composition and structure of these semiarid grasslands has changed, mostly the result of dramatic increases in native woody species (Johnston 1963, Archer et al. 1988, Archer 1989). Most of this change to brushy thorn-scrub woodland is apparently due to anthropogenic forces, primarily overgrazing by domestic livestock and fire suppression (Correll and Johnston 1970, Archer et al. 1988, Ruthven et al. 2000, Van Auken 2000, Ruthven 2001). These well-armed species are common throughout the arid and semi-arid environments of the South Texas Plains and the Edwards Plateau (Isely 1998), and along with *Prosopis glandulosa* are important sources of animal fodder, fuel, and timber (Fagg and Stewart 1994).

Thorn-scrub vegetation is common on much of Harris Ranch, which is located in the southern foothills of the Edwards Plateau in the northern part of Uvalde County, Texas. Two distinct thorn-scrub communities were encountered, a lowland community dominated by *Senegalia wrightii/Ziziphus obtusifolia*, and an upland community dominated by *Senegalia berlandieri/Opuntia engelmannii/Vachellia rigidula*. The objective of this study was to examine the structure and composition of these two thorn-scrub woodland communities on the Harris Ranch to understand better the importance, distribution, and habitat preferences of thorny legume species.
METHODS

Study Area: Harris Ranch is located near Cline, 20 miles west of Uvalde, Uvalde County, Texas at the northern edge of the South Texas Plains ecological region in the foothills of the Edwards Plateau. Managed by the Texas A & M University, Agricultural Research and Extension Center, Uvalde, the ranch is not deer-proof fenced, about 6,764 ha in size, and utilizes a cattle stocking rate of one animal unit to 35 ha (Cooper et al. 2008). Hot summers and mild winters characterize the climate of Uvalde, Texas. In a typical year the temperature varies from 4°C (40°F) to 36°C (97°F), and is rarely below -1°C (31°F) with a growing season of 250 to 365 days. The mean annual precipitation (96 year record) is 61.7 cm distributed bimodally with peaks occurring in late spring (May-June), and early fall (September-October). Short-term periods of drought are common and rainfall can be highly variable with annual extremes from 23.6 cm to 114.4 cm (Owens et al. 2002). Topography is gently rolling with the average elevation about 350 m above mean sea level.

Survey Procedures: During the summer of 2003 the two thorn-scrub woodland communities were studied. Both sites were nearly level areas with minimal disturbance other than grazing. At each site a line transect was randomly established near the center of the long axis of each community. At 30 m intervals along the length of the transect, circular plots 0.03 ha in size were located (10 plots) and all woody plants and succulents greater than 0.4 m tall were identified and their height and average crown diameter determined to the nearest dm. Data from the plots were used to determine density, average cover, relative density, relative cover, and importance value (IV) for each species at each site. The IV is calculated as the sum of the relative density and relative cover (Seigler et al. 2007).

Floristic Composition: Harris Ranch was visited five times during the growing seasons of 2002 to 2005. During these visits voucher specimens of all vascular plant species observed in and around each of the study sites, were collected, identified, and deposited in the herbarium of the University of Illinois, Urbana, Illinois (ILL). As both sites were heavily grazed most collections were from habitat not accessible to cattle. Nomenclature follows Jones et al. (1997), exotic species follows Nesom (2010).

RESULTS

At both study sites, Senegalia species dominated and accounted for at least 25% of the total importance value (total possible IV of 200). The upland community, on the thin soils of calcareous ridges and caliche cuestas, was dominated by Senegalia berlandieri (guajillo), Opuntia engelmannii (prickly pear), and Vachellia rigidula (blach bush). These three species accounted for more than 90% of the total IV, the remaining 10 species being uncommon (Table 1). The lowland community, on the relatively deep alluvial soil of a shallow valley with a small stream, was dominated by Senegalia wrightii (Wright’s senegalia) and Ziziphus obtusifolia (lofebush, gumdrop tree). These two species, with IV’s of 57.9 and 31.4 respectively, accounted from about 45% of the total IV. In this community, four other species (Condalia hookeri, Quercus virginiana, Colubrina texensis, Prosopis glandulosa) had IV’s greater than 10, the remaining 11 species being uncommon (Table 2).

The number of woody and succulent species recorded for the two thorn-scrub woodland sites ranged from 13 to 18 with a total of only 21 different species recorded. Of the 21 species encountered, 10 occurred on both sites: Aloysia gratissima (white bush), Berberis trifoliata (agarito), Condalia hookeri (brazil), Condalia spathulata (squaw-bush), Diospyros texana (Texas persimmon), Forestiera angustifolia (narrowleaf forestiera), Leucophyllum frutescens (purple sage), Opuntia engelmannii (prickly pear), O. leptocaulis (tasajillo), and Schaefferia cuneifolia (desert yaupon). Proposis glandulosa, a common species that usually dominates thorn-scrub woodlands, was only encountered in the lowland thorn-scrub community, but was common on parts of Harris Ranch.
Diversity was relatively low with only 121 species of vascular plants encountered (Appendix I). No fern, “fern-allies” or gymnosperms were collected. Of the taxa encountered, 23 were monocots in four families, and 98 were dicots in 37 families. Non-native (exotic) species accounted for five taxa, about 4% of the species collected. As is typical of prairie and thorn-scrub vegetation, Poaceae was the most common family with 19 species, Asteraceae was second with 17 species. No state endangered or threatened species were encountered.

**DISCUSSION**

The thorn-scrub vegetation of Harris Ranch and surrounding area was representative of that associated with the foothills and much of the uplands of the Edwards Plateau and the adjacent South Texas Plains (Correll and Johnston 1970, Van Auk 2000, Owens et al. 2002). In much of this rangeland, *Prosopis glandulosa* was the dominant species, with about 10 to 15 other woody or succulent, mostly armed species, varying in abundance and composition. This woodland community, where dominant trees were 3 m tall and formed a 26-60% canopy, would be equivalent to the Deciduous Woodland, Mesquite-Huisache Series (*Prosopis glandulosa-Vachellia farnesiana*) of Diamond et al. (1987) with other thorny legume species replacing huisache (*V. farnesiana*). Also referred to as the mesquite/mixed acacia savanna, this community varies extensively in overstory composition with *Prosopis glandulosa* not always present or only in low concentrations.

In south central Texas the dominant woody species of these thorn-scrub communities is mostly *Prosopis glandulosa*, but various species of the genera *Senegalia* and *Vachellia* are also common, and may dominated, sometime with a total lack of *Prosopis glandulosa*. The common species of these two genera in Texas include *Senegalial berlandierii* (=*Acacia berlandierii* (guajillo, fern acacia)), *S. greggii* (=*Acacia greggii* (catclaw acacia)), *Vachellia bravoensis* (=*Acacia schaffneri* var. *bravoensis* (huisachillo), *V. farnesiana* (=*Acacia farnesiana* (huisache)), and *V. rigidula* (=*Acacia rigidula* (blackbrush)) (Seigler et al. 2007, 2011). At Harris Ranch, *Prosopis glandulosa* was not the dominant woody species, being replaced by other woody legumes.

*Senegalia berlandierii*, along with lesser amounts of *Vachellia rigidula*, dominated limestone ridges and calciche cuestas of the Harris Ranch (Table 1). This community, in which the dominants were shrubs or small trees 0.5 to 4 m tall, and formed 26 percent of more of the total canopy, would be equivalent to the Deciduous Shrubland, Blackbrush Series (*Vachellia rigidula*) of Diamond et al. (1987). *Vachellia rigidula* appeared to be fairly site specific at the Harris Ranch being restricted to the calcareous ridges. This species appears to be well adapted to dry sites with high levels of available calcium. *Senegalia berlandierii*, in contrast, was a component of disturbed habitats, often along roadsides and in arroyos, but also an important stand component on the limestone ridges. Common throughout southern and western Texas, this species is abundant on limestone ridges and calciche cuestas (Correll and Johnston 1970, Isely 1998, Seigler et al. 2007, 2011).

*Senegalia wrightii* was the dominant species in the thorn-scrub woodland community on alluvial soil at Harris Ranch (Table 2). This taxon is closely related to *S. greggii* and has, in the past, been considered a variety of *S. greggii* (Isely 1969). *Senegalia berlandierii* and *S. wrightii* occasionally hybridize, producing the uncommon *S. x turnerii*. A population of this hybrid was observed at Harris Ranch on a hillside near the *S. wrightii* thorn-scrub community. On this hillside, both parental species were encountered along with numerous individuals of the resulting hybrid (Seigler et al. 2012).

A species of calcareous soils, *Senegalia wrightii* is known from near sea level to about 800 m in southern Arizona and southwestern Texas in the United States, and the states of Baja California Sur, Chihuahua, Coahuila, Nuevo Leon, and Tamaulipas, Mexico. Until this study, we have never seen an extensive population of *S. wrightii*, generally finding one, or a few individuals along roadsides, in
pastures, or other disturbed areas. In this thorn-scrub community many individuals exceed 3 m in height: *S. wrightii, Quercus virginiana,* and *Celtis laevigata.* The remaining species were mostly less than 2 m tall. *Prosopis glandulosa,* sixth in IV, was mostly present as small individuals rarely exceeding 2 m tall.

Though some of the acacia species at Harris Ranch have distinct habitat preferences, the reason for their continued importance and the continued prevalence of thorn-scrub woodland communities they dominate is not entirely clear. Most information suggests that overgrazing and fire suppression were the primary causes of this encroachment (Lehmann 1969, Van Auken 2000). When much of the South Texas Plains and the Edwards Plateau was covered with open savanna containing a dense groundcover of grasses and forbs, wildfires were frequent and of sufficient intensity to prevent encroachment by native woody species. However, overgrazing by livestock reduced the fuel load. At the same time, fire suppression allowed for a significant decrease in fire frequency creating ideal conditions for the rapid expansion of native invaders. Presently, prescribed burns are being used as one way to reduce shrub and tree densities and increase the extent of prairie (Owens et al. 2002). These fires may not be of sufficient intensity and frequency to reduce the extent of thorn-scrub woodlands significantly.

**ACKNOWLEDGEMENTS**

We wish to acknowledge support of this work by a grant from the International Arid Lands Consortium (O1R005), a grant from the National Science Foundation (NSF DEB 04-15803), and to thank the Texas Parks and Wildlife Department, and in particular D. C. Ruthven, J. F. Gallagher, and D. R. Synatzske of the Chaparral Wildlife Management Area, and M. K. Owens with the Texas Agricultural Experiment Station for their assistance with the project. We also appreciate the critical review of the manuscript by Dr. David Riskind, Texas Parks and Wildlife Department, Austin, and William McClain, Adjunct Research Associate in Botany, Illinois State Museum, Springfield, Illinois.

Appendix I. Vascular plant species encountered at Harris Ranch near Cline, Uvalde County, Texas are listed alphabetic by families. The material was collected during five field trips to the ranch between 2002 and 2003. Collecting numbers after each name are those of D.S. Seigler, and are deposited in the herbarium of the University of Illinois (ILL). Except for the genus Acacia s.l. nomenclature follows Jones et al. (1997). The members of the genus Acacia s.l. are separated into their presently recognized genera: Senegalia and Vachellia. A few species were not collected and are listed as observed in this list. Note: *= exotic species.
