Routine identification of Mexican plants has revealed the following novelty:

SALVIA CLARKCOWANII B.L. Turner, sp. nov. Fig. 1

Salvia purpurea Ort. similes sed differt foliis majoribus petiolis longioribus (plerumque 4-10 cm longis vs 1-4 cm), calycibus valde purpureis ad apices expansis, et corollas glabris vel paene glabris.

Perennial shrublets or shrubs 1-3 m high. Stems minutely pubescent with down-swept hairs. Leaves mostly 9-18 cm long; petioles 3-10 cm long; blades broadly ovate to subcordate, glandular-punctate beneath, minutely pubescent on both surfaces, mostly along the major veins, their margins serrate. Spikes terminal, arranged in pseudocorymbose panicles 6-15 cm high, 5-10 cm across. Flowers 4-10 to a node, the pedicels mostly 3-4 mm long. Floral bracts persistent, lanceolate to ovate, 1-2 mm long, 0.5-1.0 mm wide. Calyces (flowering) 7-9 mm long, 2-lipped, the upper lip 3-veined and somewhat shorter than the bifid lower lip, at maturity their apices becoming purple and expanded, minutely pubescent with both short hairs and globular glands. Corollas purple, arcuate in bud; tubes 20-25 mm long, not papillose within; upper lip 6-10 mm long, glabrous, ca twice as long as the lower. Stamens excurrent from the upper lip for 4-8 mm; filaments 10-16 mm long; anthers yellow, ca 2.5 mm long. Styles long and slender, extending ca 10 mm beyond the upper lip, glabrous or nearly so, the upper branch 2-3 times as long as the lower. Nutlets ovoid, brown, glabrous, ca 2 mm long, 1.5 mm wide.

ADDITIONAL SPECIMENS EXAMINED: MEXICO. GUERRERO: Mpio. Apaxtla de Castrejon, “1.5 km al SE de Puerto de El Gallo, Carr. a Atoyac.” ca 2320 m, 22 Feb 1985, Tenorio 8051 (TEX); Mpio. Atoyac de Alvarez, 10 km SW of Puerto del Gallo, ca 2100 m, Martínez S. et al. 6191 (TEX).

The present taxon was given the unpublished name *S. nicolsoniana* by Ramamoorthy. I independently discerned its novelty upon examination of type material; indeed, Cowan himself noted on the margin of a newspaper containing type material, that the collection was undescribed, but he had not “decided on [a] name.” I prefer to name the taxon for the collector himself, who first collected the taxon and recognized its novel status. Clark Cowan was a graduate student at The University of Texas, Austin for several years during which time he collected extensively in Mexico. He also collaborated with the present author on a systematic study of the genus *Stemodia* (Turner and Cowan 1993). He is currently involved with botanical studies on Santa Rosa Island, California, working out of the University of California, Santa Barbara.

*Salvia clarkcowanii* appears to belong to the sect. Purpureae of Epling (1939). While compared in the Latin diagnosis with the widespread, commonly encountered, *S. purpurea*, it is perhaps closest to *S. eizi-matudae* Ramamoorthy of Chiapas, Mexico, the taxa having similar foliage, calyces, and corollas.

**ACKNOWLEDGEMENTS**

I am indebted to my friend and colleague Guy Nesom for the Latin diagnosis and helpful comments on the article itself.
